1 Chapter 1: Why This Dataset and Why Visualization

1.1 Why This Dataset Was Chosen

The Global Findex 2025 shows how mobile technology is assisting more adults worldwide to own and use financial accounts to participate in the internet and financial system. This is the world's first most comprehensive database on digital and financial inclusion and the only global source of comparable demand-side data (data collected directly from adults through surveys). The Global Findex 2025 serves as a vital resource for policymakers working on digital connectivity and financial inclusion, as well as for researchers, practitioners, and development experts. The database was investigated by Development Research Group, Finance and Private Sector Development Unit in affiliation with World Bank and was produced by Gallup, Inc. The dashboard is based on the Global Findex 2025 microdata for Vietnam. Data was collected through face-to-face household interviews conducted between June 23 and August 31, 2024. A nationally representative sample of 1,000 individuals aged 15 years and older was obtained using a multistage probability sampling design. Survey weights were applied to correct for unequal selection probabilities and nonresponse bias, ensuring that estimates are representative of Vietnam's adult population. The survey has an approximate design effect of 1.33 and a margin of error of ± 3.6 percentage points.

- Q1. The Socioeconomic Exclusion Bottleneck:** Which specific intersecting demographic cohorts (cross-referenced by income quintile, gender, education, and rurality) remain entirely excluded from the formal financial framework, and what specific institutional friction logs (e.g., cost, distance, trust, or missing documentation) drive these unbanked constraints?
- Q2. The Digital Infrastructure Leapfrogging Paradox:** Is mobile money successfully expanding financial inclusion by reaching previously unbanked populations, or is it primarily serving as a secondary transaction tool for urban citizens who already have access to traditional banking?
- Q3. The Financial Inflow Digitization vs. Liquidation Vector:** How effectively do formal wage channels and public transfer frameworks digitize incoming financial flows, and what structural factors cause users to immediately liquidate these digital inflows into cash?
- Q4. Consumer Protection and Digital Literacy Gaps:** How does rapid smartphone and internet adoption across vulnerable, low-income or rural demographics correlate with exposure to digital scams, and does a lack of digital literacy create new security risks?

Q5. Intersectional Financial Resilience Strategies: How do financial access levels affect a household’s ability to handle sudden economic shocks, and do marginalized groups rely more on formal savings or informal, high-risk community debt networks when facing a crisis?

1.2 Role of Visualization in the Problem

The Vietnam Financial Inclusion Dashboard 2025 is designed as an institutional, five-page interactive policy workspace. Its structure converts 1,000 high-dimensional, weight-adjusted individual records from `Findex_Microdata_2025_updateViet Nam.csv` into five connected thematic layers. That design allows the reader to isolate structural inequalities, trace transaction flows, and diagnose exclusion barriers across the Vietnamese financial ecosystem.

Figure 1: Page 1 overview: the macro-socioeconomic baseline.

Figure 1: Page 1 macro-socioeconomic baseline. The dashboard begins with a demographic and structural baseline. This page presents country-level KPI cards such as urban concentration, secondary education thresholds, and workforce participation, together with cross-tabulated population views. It appears first because later financial indicators only

make sense when read against the country's underlying social composition.

Figure 2: Page 2 overview: connectivity and digital readiness.

Figure 2: Page 2 connectivity overview. After the demographic baseline is established, the dashboard moves to connectivity and digital readiness. This page tracks internet-use depth, smartphone ownership, and foundational versus online identity coverage so the reader can determine whether weak financial participation begins as an infrastructure problem or persists despite high digital access.

Figure 3: Page 3 overview: the default account-ownership and access state.

Figure 3: Page 3 default account-access state. The narrative then moves to the account ownership and access landscape. This page reports formal banking and mobile money inclusion, shows how rural and urban groups distribute across banking tiers, and benchmarks the concrete frictions faced by the unbanked. It marks the transition from technical readiness to formal institutional inclusion.

Cash Flows & Digitalization Vectors

National Digitization of Financial Inflows: Cash vs Digital Delivery

Receive Payment Method ● Cash Only ● Digital (Direct to Account) ● Other Methods ● Unknown

Utility Payment Methods by Geography

Location ● Rural ● Urban

Digital Merchant and In-Store Payment

● Merchant Payments ● In-Store Digital Pay

Why Consumers Stick to Cash-Only Transactions

Figure 4: Page 4 overview: cash flows and digitization vectors.

Figure 4: Page 4 cash-flow overview. The next step tests whether account access actually changes daily transaction behavior. This page compares cash versus digital delivery across wages, agricultural sales, transfers, utility payments, and merchant transactions. It helps the reader move beyond access rates and ask whether account holders remain trapped in cash-heavy routines.

Figure 5: Page 5 overview: financial health and resilience.

Figure 5: Page 5 resilience overview. The final page brings the earlier layers together by asking how households cope with economic shocks. It connects demographics, technology, access, and transaction behavior to measures of saving, borrowing, and emergency coping channels. This page is placed last because financial resilience can only be interpreted after the structural and behavioral context is already clear.

1.3 Types of Visualization Used

The dashboard uses a hybrid visualization strategy to match the needs of policy analysts, development researchers, and decision-makers who need both a clear narrative and the ability to test subgroup conditions directly.

The explanatory layer functions as an anchored narrative. Its fixed five-page sequence guides the reader through one policy argument: genuine financial inclusion cannot be evaluated by account access alone, but must be assessed through structural context, digital readiness, transaction behavior, and household resilience. National benchmarks, large labels, and stable page order keep that storyline legible from beginning to end.

The exploratory layer gives the user room to depart from the national story and investigate specific demographic conditions. Page-level Power BI filters on Page 3 and Page 5, together with hover tooltips and linked visual updates, let the reader ask more

precise questions about rural disadvantage, gender gaps, or income-based exclusion without leaving the broader policy frame.

Typology	Characteristics
Explanatory layer	Fixed five-page narrative; static national benchmarks; curated policy-facing layout.
Exploratory layer	Dynamic multi-criteria slicers; user-led demographic drill-downs; interactive details-on-demand.

Table 1: Hybrid explanatory and exploratory typology used in the dashboard.

Figure 6: Page 3 filtered state for the subgroup Rural + Female + Poorest 20%.

Traditional visualization theory often recommends separating exploratory tools from explanatory presentation so that the user is not pulled away from the main story too early. This dashboard deliberately relaxes that rule by embedding multi-criteria filters directly inside the narrative workspace, especially on *Figure 6: Page 3 filtered subgroup state*. That choice is justified because financial inclusion is inherently intersectional: policymakers need to isolate cohorts such as rural low-income women and then observe how the exclusion profile changes relative to the national baseline. The combination of explanatory sequencing and exploratory filtering therefore makes the dashboard more useful for real policy diagnosis than either approach would be on its own.

2 Chapter 2: Data Types, Marks, and Channels

2.1 Techniques / Principles Applied

- Classifying variables as nominal, ordinal, or quantitative before encoding them.
- Selecting marks that fit the analytical task: cells, bars, flows, and lines.
- Prioritizing precise channels such as aligned position and length for the most important quantitative comparisons.
- Using color, width, and enclosure as supporting channels rather than the primary source of exact comparison.

2.2 How Applied in the Dashboard

2.2.1 Classifying Variables Before Encoding

The dashboard first separates variables by role before assigning any visual form.

The Socioeconomic Matrix (Income vs. Education)

Figure 7: The socioeconomic matrix (income vs. education).

Figure 7: Socioeconomic matrix treats income quintile and education as ordered categories and uses grid cells positioned by row and column to compare their intersections. Weighted population density is then encoded through a sequential blue scale, which is appropriate because the page needs to reveal concentration patterns rather than only isolated totals.

Figure 8: Mobile ownership rate by location, phone type, gender, and income group.

Figure 8: Mobile ownership profile combines subgroup categories such as location, gender, and income group with phone type and access rate. Grouped bars and aligned lengths support accurate comparison across small multiples, while hue separates basic phones from smartphones without changing the baseline used for quantitative reading.

The Account Composition Flow

Figure 9: The account composition flow.

Figure 9: Account composition flow treats location and account ecosystem type as nominal structural states connected by flows. Nodes, horizontal position, ribbon width, and grouped color are used to show how the population distributes across account conditions, which is more important on this page than exact pairwise magnitude reading.

Figure 10: The national digitization of financial inflows: cash vs. digital delivery.

Figure 10: National inflow digitization treats inflow type as nominal categories and payment method as composition within each category. The segmented 100% stacked bars use aligned position and segment length to show how wages, sales, pensions, and transfers split across cash, direct-to-account, and other methods.

Figure 11: Save vs. borrow percentage overlays.

Figure 11: Save vs. borrow trajectories treats income group and income runway as ordered categories, while save and borrow rates are quantitative values. Vertical position carries the main comparison and hue separates the two behaviors, making directional change across ordered groups easier to track.

2.2.2 Selecting Marks for the Analytical Task

The chosen marks follow the main question on each page. *Figure 7: Socioeconomic matrix* uses matrix cells to compare ordered categorical intersections, *Figure 8: Mobile ownership profile* uses grouped bars for subgroup rate comparison, *Figure 9: Account composition flow* uses ribbons and nodes to emphasize movement between account states, *Figure 10: National inflow digitization* uses segmented bars for within-category composition, and *Figure 11: Save vs. borrow trajectories* uses line overlays to highlight directional change across ordered groups.

2.2.3 Prioritizing Position and Length for Exact Comparison

Where precise reading matters most, the dashboard relies on aligned position and length. *Figure 8: Mobile ownership profile* makes subgroup gaps easy to compare because all bars share common baselines, while *Figure 10: National inflow digitization* lets readers compare the dominant payment mode within each inflow category. Even in *Figure 7: Socioeconomic matrix*, ordered row and column position do the main structural work before color is used to show density.

2.2.4 Using Supporting Channels Carefully

Supporting channels are kept secondary to the main quantitative comparison. *Figure 7: Socioeconomic matrix* uses sequential blue intensity to signal weighted density, *Figure 9: Account composition flow* uses ribbon width and grouped color to organize structural flows, and *Figure 11: Save vs. borrow trajectories* uses hue to distinguish saving from borrowing once the reader has already located the values by position.

2.3 Notes / Adjustments

On Page 5, *Figure 11: Save vs. borrow trajectories* plots rates with a line-chart layout across ordered income quintiles and income runway categories. Strict visualization theory usually reserves continuous lines for truly continuous or time-series data, so connecting ordinal groups can imply intermediate values that do not actually exist.

This dashboard keeps the line marks deliberately because they exploit spatial continuity to make the behavioral trajectory easier to read. The lines show that saving rises while borrowing falls as economic position improves, and that contrast would be less legible in a denser bar-based layout. The adjustment is therefore a controlled trade-off: it relaxes strict categorical encoding in order to reveal the structural crossover between two financial strategies more clearly.

3 Chapter 3: Pre-Attentive Processing, Gestalt Principles, and Magnitude Estimation

3.1 Techniques / Principles Applied

- Pre-attentive processing through contrast, saturation, and enclosure.
- Gestalt grouping, especially proximity, similarity, and enclosure.
- Magnitude estimation that favors common baselines and linear length for important comparisons.

3.2 How Applied in the Dashboard

3.2.1 Pre-attentive Processing

Pre-attentive pop-out is used to direct attention before detailed reading. On Page 1, *Figure 7: Socioeconomic matrix* uses darker blue cells to make high-density income–education intersections stand out quickly. On Page 2, *Figure 8: Mobile ownership profile* differentiates smartphone and basic phone rates with strong luminance contrast, so the penetration gap is visible without a full label-by-label scan.

3.2.2 Gestalt Grouping

Figure 12: The Account Ownership & Access Landscape KPI cards.

Figure 13: Filter controls on the Account Ownership & Access Landscape page.

Gestalt grouping is especially visible on Page 3. *Figure 12: Page 3 KPI cards* clusters the four KPI cards closely together, so proximity signals that they belong to the same summary layer. *Figure 13: Page 3 filter bar* adds enclosure by separating the controls from the charts they drive, making the interaction layer visually legible before the user reads any labels in detail.

3.2.3 Magnitude Estimation

Magnitude estimation is handled conservatively in the comparison-heavy charts. *Figure 8: Mobile ownership profile* and *Figure 16: Exclusion friction log* rely on bar length and aligned baselines because those channels are more accurate for comparing rates than area- or angle-based alternatives.

3.3 Notes / Adjustments

The Account Composition Flow in *Figure 9: Account composition flow* is less precise than a standard bar chart for direct magnitude comparison. The trade-off is accepted because the page needs to emphasize relationships between source groups and account states, not only isolated totals.

4 Chapter 4: Chart Types for Amounts, Distributions, Proportions, Relationships, and Trends

4.1 Techniques / Principles Applied

- Matching chart types to amounts, distributions, proportions, relationships, and trends.
- Preferring readable 2D Cartesian layouts for most dashboard comparisons.

4.2 How Applied in the Dashboard

4.2.1 Matching Chart Types to Analytical Questions

Why Consumers Stick to Cash-Only Transactions

Figure 14: Why consumers stick to cash-only transactions.

Amounts. *Figure 14: Cash-only reasons* uses a standard bar chart to compare the weighted size of cash-only barriers. This is appropriate because the task is simple magnitude ranking, and bar length on a common baseline makes the differences easy to read.

Figure 15: The weighted population pyramid by age and gender.

Distributions. *Figure 15: Population pyramid by age and gender* and *Figure 7: Socioeconomic matrix* show how the population is distributed across age, gender, income, and education. These views are suitable because they reveal whether the sample is balanced or concentrated in specific groups before later policy comparisons begin.

Proportions. *Figure 10: National inflow digitization* uses a 100% stacked bar layout to compare payment composition within each inflow type. This chart works well when the goal is to compare how cash, direct-to-account, and other channels share the same total.

Relationships. *Figure 8: Mobile ownership profile* uses a small-multiples bar design to compare ownership patterns across location, gender, income, and phone type. The structure avoids overplotting while still showing how the variables relate to one another.

Trends. *Figure 11: Save vs. borrow trajectories* uses line overlays to show how saving and borrowing rates move across ordered income groups and income runway categories. The chart is effective for showing direction of change even though the categories are ordinal rather than continuous.

4.2.2 Preferring Readable 2D Cartesian Layouts

Across *Figure 14: Cash-only reasons*, *Figure 15: Population pyramid by age and gender*, *Figure 10: National inflow digitization*, and *Figure 11: Save vs. borrow trajectories*, the dashboard relies mainly on a 2D Cartesian coordinate system because perpendicular axes support clearer comparison than radial or 3D alternatives for this type of policy dashboard.

Statistical uncertainty is not explicitly visualized, so the charts are easy to read but can overstate precision, especially for filtered subgroup views. This matters most when the reader narrows the dashboard to a small cohort, because visually clear differences may look

firmer than the survey design can guarantee without confidence intervals or sample-size cues.

4.3 Notes / Adjustments

Figure 10: National inflow digitization emphasizes composition rather than exact comparison of every internal segment, so only the first segment in each row has a shared baseline.

Figure 11: Save vs. borrow trajectories also simplifies ordinal data into continuous-looking trajectories, which improves readability but should be interpreted as directional rather than strictly continuous change.

5 Chapter 6: Visual Integrity (Ink, Overlap, Color, Layout, and Annotation)

5.1 Techniques / Principles Applied

- Proportional ink and true baselines for quantitative marks.
- Color choices that preserve contrast and basic accessibility.
- Overlap control, annotation, and data–context balance.

5.2 How Applied in the Dashboard

5.2.1 Proportional Ink and True Baselines

The dashboard maintains proportional ink by anchoring bar charts at true zero baselines and by keeping bar length or flow width tied to the underlying weighted values. This is visible in *Figure 14: Cash-only reasons* and in *Figure 9: Account composition flow*.

5.2.2 Color and Accessibility

Color is used with restraint. *Figure 7: Socioeconomic matrix* keeps a single sequential palette so density is shown through intensity rather than extra hue variation, while *Figure 10: National inflow digitization* uses a limited set of contrasting fills to separate payment channels without turning the page into a saturated categorical display.

5.2.3 Overlap, Annotation, and Data–Context Balance

Overlap is handled through panel separation, spacing, and concise annotation. Dense views are broken into smaller comparison units, while reference titles, legends, and benchmark markers provide context without covering the data.

Figure 16: The Exclusion Friction Log: gap analysis benchmarking unbanked constraints vs. national baseline.

Figure 16: Exclusion friction log is a good example of data–context balance because the title, legend, and reference markers explain the benchmark logic without burying the chart under decorative elements.

5.3 Notes / Adjustments

Figure 10: National inflow digitization uses a 100% stacked format, so only the first segment in each row has a common baseline. That reduces precision for the inner segments, but the compromise is acceptable because the page is intended to show composition rather than exact segment-by-segment ranking.

6 Chapter 8: Interaction Techniques

6.1 Techniques / Principles Applied

- Overview first, then filter, then details-on-demand.
- Coordinated views that update several visuals from the same selection.

- Local page-level filters instead of one global interaction state.
- Power BI slicers and linked visuals as the main dashboard interaction tools.

6.2 How Applied in the Dashboard

6.2.1 Overview First, Then Filter, Then Details-on-Demand

Figure 17: List of filters on the Account Ownership & Access Landscape page.

The dashboard was built in Power BI and uses interaction mainly to extend a guided policy narrative into subgroup exploration. Users first see overview states on pages such as Account Ownership & Access Landscape and Financial Health & Resilience, then narrow the analysis through slicers, and finally use details-on-demand in the live dashboard to inspect exact values. The overview state is visible in *Figure 3: Page 3 default account-access state*, while the presence of the page-level controls is visible in *Figure 17: Page 3 filter controls*.

6.2.2 Coordinated Views That Update from One Selection

Figure 17: Page 3 filter controls shows the main interaction design on Page 3: the page starts with a national overview, then lets users filter by urbanicity, income group, gender, education level, and workforce status. Within the live Power BI dashboard, those slicers coordinate the views in *Figure 12: Page 3 KPI cards*, *Figure 9: Account composition flow*, and *Figure 16: Exclusion friction log* so that all three reflect the same selected cohort.

Figure 6: Page 3 filtered subgroup state provides direct evidence that coordinated updates occur on Page 3 after a subgroup selection. When the dashboard is filtered to Rural + Female + Poorest 20%, the KPI cards update to Banking Inclusion 41.19%, Financial Institution Account 41.19%, Mobile Money Account 20.83%, and Digital Account 29.49%. The same filtered view also reduces the income-gender chart to the selected subgroup and rebalances the Sankey and exclusion-barrier views to the same cohort, which is exactly the behavior expected from linked Power BI visuals.

6.2.3 Local Page-Level Filters

Figure 18: Filter controls on the Financial Health & Resilience page.

The exported PDF confirms the placement of the filters and the default overview state. It also supports the claim that the dashboard uses local page-level interaction rather than one global control state shared across every page. That same design pattern reappears on the resilience page through *Figure 18: Page 5 filter controls*, where the filter strip is embedded directly inside the Page 5 analysis space instead of being detached as a report-wide control layer.

6.2.4 Power BI Slicers and Linked Visuals

Figure 19: Hover tooltip on the Page 3 Sankey flow.

The main interaction tool is Power BI itself, not LaTeX. LaTeX only documents the dashboard through static figures, while Power BI provides the slicers, linked visuals, and details-on-demand behavior described in this chapter. The figures therefore demonstrate interaction design intent and control placement. *Figure 19: Page 3 hover tooltip* additionally confirms a true details-on-demand behavior on Page 3: hovering over a Sankey branch reveals the context fields *Location = Rural*, *Account Ecosystem Type = Traditional Bank Only*, and *Total Weighted Population = 12*. That is stronger evidence than a static

export alone, because it shows that the live dashboard exposes exact values and category context interactively.

6.3 Notes / Adjustments

The available evidence now goes beyond the static PDF because Page 3 includes a verified filtered state in *Figure 6: Page 3 filtered subgroup state* and a verified hover tooltip in *Figure 19: Page 3 hover tooltip*. However, the report still does not verify zoom behavior, animation, or equivalent live interaction evidence for every other page. The chapter therefore makes direct claims only where screenshots show the interaction explicitly, and keeps the remaining interaction language appropriately bounded.

7 Chapter 9: Storytelling and Presentation Narrative

This chapter reads the Vietnam Financial Inclusion Dashboard 2025 as a policy brief built from weighted survey evidence rather than as a loose collection of charts. Its central argument is that financial inclusion in Vietnam cannot be judged by account ownership alone; it must be read as a progression from social structure to digital readiness, from access to actual usage, and finally to financial resilience.

See *Figure 1: Page 1 macro-socioeconomic baseline*.

7.1 The Core Policy Story

The chapter follows one narrative spine only:

Context → Readiness → Access → Usage → Resilience

This sequence is persuasive because each page answers the most natural policy question created by the page before it. A country can appear digitally connected yet still fail to activate digital identity. It can appear broadly banked yet still settle routine transactions in cash. It can appear financially included yet still leave vulnerable households dependent on informal support when shocks arrive.

7.1.1 Page 1: Establishing the Structural Baseline

Page 1 serves as the structural baseline of the story, showing that later gaps in access and usage emerge inside an already uneven social landscape rather than in a neutral population.

The strongest evidence comes from the macro indicators and *Figure 7: Socioeconomic matrix*. The page reports an Urban Concentration Rate of only 30.33%, an In Workforce

Rate of 87.92%, and a Secondary Education Threshold Rate of 89.98%. Yet the matrix shows that the Poorest 20% group has only 6 respondents with tertiary education or more, compared with 72 in the Richest 20% group. Those numbers make inequality in income and education visible before the dashboard ever begins talking about banking.

That opening matters for the policy argument because it prevents the reader from treating later financial outcomes as purely technological problems. The story begins by showing that exclusion is already structured by geography, socioeconomic position, and educational opportunity, so any later digital or financial intervention must be judged against that baseline rather than against national averages alone.

See *Figure 7: Socioeconomic matrix*.

7.1.2 Page 2: Readiness Exists, but Activation Is Weaker

Page 2 advances the story by testing whether the population that looks demographically ready for participation is also ready to use digital financial tools in practice.

Figure 20: Page 2 readiness evidence used in the storytelling analysis.

Figure 21: Digital activity profile: penetration depth among internet users.

Figure 20: Page 2 readiness overview shows that internet access is both high and frequent: Internet Use in the last three months reaches 87.85%, while Internet Use in the last seven days remains close at 85.39%. The same figure also shows a sharp activation gap: Foundational ID coverage reaches 99.65%, Online Digital ID reaches 71.19%, but Active Digital ID Verification falls to only 32.68%. *Figure 21: Digital activity profile* pushes the

argument further: Social Media reaches 94.46% and Read News reaches 78.44%, but Gov activity is only 15.63% and Job activity is only 4.89%.

Together, these figures argue that connectivity alone is not the same as activation. Vietnam's adults appear highly present online, but their digital behavior remains much stronger in communication and information than in institutional or economic use. For a policy reader, this reframes the problem: the bottleneck is not simply device or internet availability, but the conversion of digital presence into verified, trusted, high-value use.

7.1.3 Page 3: Access Is Broad, but Not Even

Page 3 becomes the diagnostic center of the story by asking who is formally included, who is left behind, and what kind of inclusion the system is actually delivering.

Figure 22: Banking inclusion by income group and gender.

Figure 12: Page 3 KPI cards reports Banking Inclusion at 74.93%, Financial Institution Account ownership at 74.05%, Mobile Money Account ownership at 46.69%, and Digital Account ownership at 67.03%. That already shows a 27.36 percentage-point gap between financial institution accounts and mobile money accounts. *Figure 22: Banking inclusion by income group and gender* and *Figure 9: Account composition flow* then show that access is not socially neutral: lower-income groups, especially on the rural side of the account-composition flow, are more exposed to unbanked or thinner account states. *Figure 16: Exclusion friction log* adds a barrier layer to that story by showing that exclusion is not just a missing account status but a set of recurring frictions tied to money, cost, and access conditions.

See *Figure 12: Page 3 KPI cards*, *Figure 13: Page 3 filter bar*, *Figure 9: Account composition flow*, and *Figure 16: Exclusion friction log*.

The policy consequence is that high national access cannot be read as uniform inclusion. A dashboard that stopped at the 74.93% headline would suggest a largely solved problem; this page instead shows that the remaining gap is concentrated, structured, and

diagnostically meaningful. The story therefore shifts from “how many people are banked?” to “which groups remain thinly served, and what keeps them there?”

7.1.4 Page 4: Access Does Not Guarantee Digital Usage

Page 4 challenges the access story by asking whether accounts actually change how money moves through everyday life.

Figure 23: Digital merchant and in-store payment by geography.

Figure 24: Utility payment methods by geography.

Figure 10: National inflow digitization shows that Corporate/Formal Wages are mostly digitized, with 80.99% delivered directly to an account and only 18.60% cash-only. Agricultural Sales show the opposite pattern: 73.42% are cash-only and only 25.79% are delivered digitally to an account. *Figure 23: Digital merchant payments by geography* adds a geographic gap: Urban Merchant Payments reach 65.79%, compared with 50.30% in rural areas, while Urban In-Store Digital Pay reaches 62.67%, compared with 46.11% in rural areas. *Figure 24: Utility payment methods by geography* visually reinforces the same divide by showing that rural usage leans more heavily toward cash-only or non-bill-paying states than the urban profile.

See *Figure 10: National inflow digitization*.

This is the chapter's most important argumentative turn. Page 3 could have been read as a success story about account ownership; Page 4 shows why that reading is incomplete. The policy issue is not only whether people possess accounts, but whether rural payment ecosystems, merchants, and routine household transactions are digitized strongly enough for those accounts to matter in practice.

7.1.5 Page 5: The Real Test Is Resilience Under Stress

Page 5 gives the story its outcome test by asking whether participation in the financial system is associated with stronger household resilience rather than with access alone.

Figure 25: Page 5 resilience KPI cards.

Income Group	Asset Liquidation	Family & Friends	Formal Savings	Institutional Loan	Labor/Extra Work
Poorest 20%	5	86	30	2	19
Second 20%	2	57	56		42
Middle 20%	2	68	41	1	39
Fourth 20%	0	43	37	4	48
Richest 20%	2	34	60	3	51

Figure 26: Coping channels by income group.

Figure 25: Page 5 resilience KPI cards shows a national macro split in behavior: 73.05% of respondents saved, while 45.98% borrowed. That national picture is not the endpoint, however. *Figure 11: Save vs. borrow trajectories* shows that saving and borrowing move differently across income groups and income runway lengths, while *Figure 26: Coping channels by income group* reveals a much sharper difference in coping channels. In the Poorest 20% group, Family & Friends stands at 86 while Formal Savings is only 30; in the Richest 20% group, Formal Savings rises to 60 while Family & Friends falls to 34. The full page overview in *Figure 5: Page 5 resilience overview* shows how these KPI, trajectory, and coping views work together inside one resilience frame.

The final implication is that inclusion should be judged by how households absorb shocks, not only by whether they hold an account. The dashboard ends on resilience because it reveals a substantive difference between formal financial participation and fallback dependence on informal networks. That ending gives the chapter its human and policy-facing conclusion: the strongest financial systems are not just those that open accounts, but those that reduce vulnerability when households are under pressure.

7.2 Why the Sequence Persuades

The sequence persuades because it prevents the reader from jumping too quickly to a positive conclusion about inclusion. The chapter begins with structural conditions, moves through readiness and access, tests whether those conditions produce real digital usage, and only then asks whether that usage translates into resilience. The same story can still

be summarized once as *Context* → *Readiness* → *Access* → *Usage* → *Resilience*, but the force of the sequence lies in what each transition corrects.

The key corrective turn happens after Page 3. Banking Inclusion reaches 74.93%, and Financial Institution Account ownership reaches 74.05%, which could easily support a success narrative. Page 4 interrupts that reading by showing Agricultural Sales at 73.42% cash-only and Urban Merchant Payments at 65.79% versus 50.30% in rural areas. Page 5 then interrupts any remaining optimism by showing that the Poorest 20% still rely far more on Family & Friends at 86 than on Formal Savings at 30. In other words, the chapter persuades because it steadily narrows the distance between headline access and lived financial security.

See *Figure 12: Page 3 KPI cards*, *Figure 10: National inflow digitization*, and *Figure 26: Coping channels by income group*.

7.3 How the Evidence Builds the Argument

The argument is built through accumulation rather than assertion. Each page begins with a high-level anchor, then moves into a more diagnostic chart that either qualifies or complicates the headline. For example, Page 2 does not stop at high internet-use rates of 87.85% and 85.39%; it contrasts them with Active Digital ID Verification at only 32.68%, then deepens the point through *Figure 21: Digital activity profile*, where Social Media reaches 94.46% but Gov activity is only 15.63%. That sequence turns a connectivity story into an activation story.

The same evidence-building logic continues in later pages. Page 3 moves from the 74.93% banking headline to social segmentation and exclusion barriers. Page 4 moves from digital wage inflows at 80.99% to the much weaker rural and agricultural usage environment. Page 5 moves from a national Saved rate of 73.05% to the more revealing contrast between Family & Friends at 86 and Formal Savings at 30 for the Poorest 20%. Because each visual layer narrows the meaning of the previous one, the reader is led toward a more cautious and policy-useful interpretation of inclusion.

See *Figure 20: Page 2 readiness overview*, *Figure 21: Digital activity profile*, *Figure 12: Page 3 KPI cards*, *Figure 24: Utility payment methods by geography*, and *Figure 26: Coping channels by income group*.

7.4 Narrative Style and Claim Discipline

The narrative style is persuasive, but it stays disciplined by grounding every major interpretation in visible comparison rather than in speculative language. The chapter does not claim that digital access *causes* resilience or that cash usage *proves* exclusion. Instead, it repeatedly uses measured gaps to show where the financial system appears stronger,

where it appears weaker, and which groups or settings deserve closer policy attention. That is why the tone works better as a policy brief than as a promotional story.

This discipline matters most where the chapter could easily overstate its case. The gap between Online Digital ID at 71.19% and Active Digital ID Verification at 32.68% supports a claim about weaker activation, not a claim that connectivity has failed altogether. The contrast between Formal Wages at 80.99% direct-to-account and Agricultural Sales at 73.42% cash-only supports a claim about uneven digitization, not a claim that all rural finance is static. Likewise, the Poorest 20% reliance on Family & Friends at 86 versus Formal Savings at 30 supports a claim about vulnerability, not a deterministic claim about all low-income households. The chapter is most credible when it keeps that distinction clear.

See *Figure 21: Digital activity profile*, *Figure 10: National inflow digitization*, *Figure 23: Digital merchant payments by geography*, and *Figure 25: Page 5 resilience KPI cards*.

7.5 Interaction as Policy Exploration

The chapter’s policy argument is strengthened by interaction because the dashboard does not force the reader to stop at the national averages used in the narrative. Page 3 begins with Banking Inclusion at 74.93%, Financial Institution Account ownership at 74.05%, Mobile Money Account ownership at 46.69%, and Digital Account ownership at 67.03%, then gives the user filters for Urbanicity, Income Group, Gender, Education Level, and In Workforce. Page 5 does something similar from a resilience baseline of 73.05% saved and 45.98% borrowed, using filters for Location, Gender, and In Workforce to move the reader from national averages into subgroup patterns.

This interaction design matters because the chapter’s most important claims are distributional. The national story says that digital activation is weaker than connectivity, that account access is broader than digital usage, and that resilience differs across social groups. The filters on Page 3 and Page 5 make those claims investigable instead of merely rhetorical. At the same time, the available source is still a static PDF export, so the report should only claim that the dashboard is *designed for* subgroup exploration, not that every filtered result has been directly tested from the exported file.

See *Figure 13: Page 3 filter bar*, *Figure 18: Page 5 filter controls*, *Figure 3: Page 3 default account-access state*, and *Figure 5: Page 5 resilience overview*.
